WiFi coverage is almost never uniform in terms of its coverage and power. Depending on where you place your router, you may be able to cover your entire home with a strong WiFi signal or struggle to cover a single room. Unless you have a way to analyze WiFi coverage, it's easy to spend many hours guessing, struggling to find the perfect place for your router. To analyze WiFi coverage, you can download a professional application for wireless site surveys, be NetSpot, or you can go with a WiFi app for Android that has some of the same features as NetSpot and other full WiFi analytics apps. NetSpot's main advantage is its ability to generate a comprehensive thermal network map with just a few clicks, clearly highlighting all areas with low signal power. In addition to generating signal-intensity thermal maps, NetSpot can instantly detect all nearby wireless networks and display all the essential information about them. But if your needs are relatively modest, some of the best android wifi analyzer apps can do the job as well as NetSpot. The main advantage of WiFi apps for Android is their mobility. It's much easier to carry a lightweight smartphone than a much harder laptop, especially if you need to analyze wireless networks, taking multiple measurements each time. If you want to analyze the wifi signal strength of your router, then you can do so using your Android smartphone. There are some apps that allow you to do this and here we have the best app that allows you to do that. These apps will allow you to analyze Wifi signal strength and they are completely free, so you don't have to spend a single penny on it. Read also: Improve WiFi Range, Speed, and Wifi Analyzer Connectivity This app is the first to appear when you search for Wifi Analyzer apps in the Google Play Store. This app is free and works perfectly with all routers and WiFi systems. This app displays the data in a graphic form. If you want Wifi to analyze data in a graphic form, then this app is best for you. This app analyzes the Wifi signal data and shows you the result in graphic form. There are a lot more features inside the settings to tweak and get custom results if you want. Download WiFi Analyzer – WiFi Test & WiFi Scanner This application is another tool to do this, but in a simple and understandable way, so that every computer failure can understand the results. It comes with a speed tester and a channel tester too so you get the full package with the app. This app shows the power of the currently connected WiFi network. It shows power in real time, so if you move your phone around, it shows live power right there. This shows strength in a percentage way. Download WiFi Analyzer - Network Analyzer Wifi Analyzer is an application that comes with all the right tools to check the power of your WiFi network. It works with all the bands, so you don't have to worry about the tape you're using from the router. This app shows power for multiple Wifi networks at once, so you can analyze multiple networks at once. This app comes with in-depth analysis too if you want it, so you know which channel is the best h for router and Wifi network to get the best power in our place. Download Wrapping up These were the app that will turn your phone into a live Wifi power analyzer. If you know any different app from the ones you've used for yourself, then tell us in the comments. Read also: Sharing WiFi without sharing your password When setting up a wireless network, coverage is rarely even. Various obstacles, such as furniture and walls, lose the signal as they pass through them, as well as interference caused by other wireless networks nearby. The WiFi signal also becomes weaker and weaker the further away it moves from the (for example, your router). Only when you have a strong enough signal can you enjoy fast download speeds, no delayed Skype conversations, and web browsing without constantly waiting for pages to load. To have a strong signal wherever you need it, it's essential to choose an optimal place for your router and set it up in a way that will deliver the best results. But selecting a good place for a router and its configuration cannot be accessed without access to the correct information. Namely, a visual map of your router's wireless coverage and information about other WiFi networks in the area. WiFi signal intensity meter applications detect and analyze wireless networks, displaying information about their configuration and security, and some can also view wireless network signal strength as convenient thermal maps, helping you decide where it would be best to place your router. TierneyMJ/Shutterstock If the internet seems slow or web pages do not load, the problem could be the Wi-Fi connection. Maybe you're too far from the source, or the thick walls block the signal. Here's to check the precise wi-fi signal strength. Why Wi-Fi signal strength matters A stronger Wi-Fi signal means a more reliable connection. This is what allows you to take full advantage of the internet speeds available to you. The wi-fi signal strength depends on a variety of factors, it would be how far you are from the router, whether it's a 2.4 or 5ghz connection and even the materials of the walls around you. The closer you are to the router, the better. While 2.4ghz connections still diffuse, they may have interference problems. Thicker walls of thicker materials (such as concrete) will block a Wi-Fi signal. A weaker signal, on the other hand, leads to lower speeds, abandonments, and (in some cases) total disconnection. Not every connection problem is the result of poor signal strength. If the internet on your tablet or phone seems slow, start by restarting your router if you have access to it. If the problem persists, the next step is to check if Wi-Fi is the problem. Try using the Internet with a device connected via ethernet. If you're still having problems, the network is the problem. If the ethernet connection is good and resetting a router didn't help, then it's time to check the signal strength. Check wi-fi Signal Strength the Easy Way To check the wi-fi power, the first thing you need to do is look at the device that's in trouble. Whether using iOS, Android, Mac, or Windows, you should have a Wi-Fi connection indicator. Typically, four or five curved lines make up the Wi-Fi symbol, and more, which are filled, the stronger the connection. Each phone, tablet, and laptop is different and can indicate a different Wi-Fi power. But it's worth consulting with a second, or even a third device. If you've checked a phone, consider testing a tablet. Compare Internet performance on both devices and see what they display for Wi-Fi power. If you have similar results to both, you have an excellent base to use. If you have determined that the Wi-Fi connection is weak in a certain place, the next thing you need to do is to walk around and pay attention to the Wi-Fi bars on your smartphone or tablet. Keep track of how far you are from the router, and how many walls there are between her and you. Pay attention to when Wi-Fi bars rise and fall. It's a rudimentary check, but in most cases, it'll be enough. Enough. The more advanced (and accurate) method to check wi-fi power looking at the bars in a symbol will only tell you so much. If you want to dig deeper into Wi-Fi power, you'll need to use an app or program (such as the AirPort Utility app or Wi-Fi Analyzer) to measure its decibels relative to a milliwatt (dBm). You can measure a Wi-Fi signal in several ways. The most accurate measurement is milliwatts (mW), but it is also the hardest to read due to the number of decimal places (0.0001 mW). Received signal intensity indicator (RSSI) is another option, but Wi-Fi providers also deal with different scales inconsistently. Decibels in relation to milliwatt (dBm) avoid these problems, and many manufacturers convert RSSI to dBm anyway, so we will cover this measurement. The first thing to know is that dBm measurements will be displayed in negative numbers. The scale ranges from -30 to -90. If you see -30, you have a perfect connection and you're probably near your Wi-Fi router. However, if a Wi-Fi signal listed at -90 on the spot, the service is so weak, it probably can't connect to that network. An excellent connection is -50 dBm, while -60 dBm is probably good enough to flow, handle voice calls, and everything else. To measure Wi-Fi signal strength on your phone or tablet, you can use the Airport Utility app for iPhone and iPad or Wi-Fi Analyzer for Android. Both are easy to use and show results for any wireless networks in your area. For iPhone users, the Airport Utility app does not require you to access your device settings and activate your Wi-Fi scanner. Just go to your iPhone or iPad settings (not app settings), tap the Airport Utility from the settings list, and then switch Wi-Fi Scanner. Now, go back to the Airport Utility app and start a scan. You will see dBm measurements expressed as RSSI. For Android users, Wi-Fi Analyzer is an easier step. Open the app and search for the networks you found. Each entry will list power as dBm. Windows 10 does not have a built-in way to view the precise strength of the signal, although the netsh wlan interface command shows you signal strength as a percentage. In the past, we have recommended NirSoft WifiInfoView to inspect Wi-Fi channels, and also gets nod for checking Wi-Fi power. The program is free, easy to use and does not require installation. Unzip and double-click the EXE file. Just like Mac and iOS, you'll find dBm metrics listed under the RSSI entry. On Your Mac, you don't need to download any programs or apps if you want to measure the connected network. Hold down the option key and click the Wi-Fi symbol. You will see dBm measurements in the RSSI entry. Improve Wi-Fi signal strength Once you know how powerful your network is, you'll have a better idea what to do to improve it. For example, if you can reach the edges of your home and still see a 60 dBm signal (or most bars), then any problems you have are not related to Wi-Fi resistance. Check for interference, consider changing channels, or upgrade a router that supports 5 GHz if the current one does not. If you walk a camera or two away from the router and discover that you are losing the signal quickly, it's time to consider the age of the router and its placement. Either the walls are very thick and dense, or the router is old and unable to diffuse very far. If you have plaster walls, consider moving the router as close as possible to the center of the house. If the router is older, it may be time to upgrade. When you do this, look for one that supports both 2.4 Wi-Fi and 5GHz Wi-Fi signals. If you have a big house, you may want to consider a mesh router. These are an easy way to boost Your Wi-Fi signal throughout your home and include other great features, such as automatic firmware updates and guest networks. Most people probably don't need a mesh network, though, and you can find cheaper routers that also offer firmware updates and customer networks. If you're not sure you need a mesh router, you might want to consider creating a Wi-Fi thermal map of your home. Heatmaps are a great way to determine where wireless is stronger and weaker with an easy to understand visually. Create a sketch of the look of your home, and then walk around while the program measures Wi-Fi power. Then color in the map to give you a general idea of Wi-Fi signal strength throughout. If you are waiting in the center of the house and the thermal map displays weak signals everywhere, it might be time for a mesh router. Unfortunately, there is no universal solution for increasing Wi-Fi signal in every home. However, if you try each of these methods, you can get the most accurate information to make an informed decision on what to do next.
